# CSC2515 Lecture 8: Probabilistic Models

Roger Grosse

University of Toronto

# Today's Agenda

- Bayesian parameter estimation: average predictions over all hypotheses, proportional to their posterior probability.
- Generative classification: learn to model the distributions of inputs belonging to each class
  - Naïve Bayes (discrete inputs)
  - Gaussian Discriminant Analysis (continuous inputs)

CSC2515 Lec8 2 / 51

## Data Sparsity

- Maximum likelihood has a pitfall: if you have too little data, it can overfit.
- E.g., what if you flip the coin twice and get H both times?

$$\theta_{
m ML} = rac{N_H}{N_H + N_T} = rac{2}{2+0} = 1$$

- Because it never observed T, it assigns this outcome probability 0. This problem is known as data sparsity.
- If you observe a single T in the test set, the log-likelihood is  $-\infty$ .

3/51

- In maximum likelihood, the observations are treated as random variables, but the parameters are not.
- The Bayesian approach treats the parameters as random variables as well.
- To define a Bayesian model, we need to specify two distributions:
  - The prior distribution  $p(\theta)$ , which encodes our beliefs about the parameters before we observe the data
  - The likelihood  $p(\mathcal{D} | \theta)$ , same as in maximum likelihood
- When we update our beliefs based on the observations, we compute the posterior distribution using Bayes' Rule:

$$p(\boldsymbol{\theta} \mid \mathcal{D}) = \frac{p(\boldsymbol{\theta})p(\mathcal{D} \mid \boldsymbol{\theta})}{\int p(\boldsymbol{\theta}')p(\mathcal{D} \mid \boldsymbol{\theta}') d\boldsymbol{\theta}'}.$$

• We rarely ever compute the denominator explicitly.

CSC2515 Lec8 4 / 51

• Let's revisit the coin example. We already know the likelihood:

$$L(\theta) = p(\mathcal{D}) = \theta^{N_H} (1 - \theta)^{N_T}$$

- It remains to specify the prior  $p(\theta)$ .
  - We can choose an uninformative prior, which assumes as little as possible. A reasonable choice is the uniform prior.
  - But our experience tells us 0.5 is more likely than 0.99. One particularly useful prior that lets us specify this is the beta distribution:

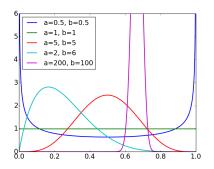

$$p(\theta; a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \theta^{a-1} (1-\theta)^{b-1}.$$

 This notation for proportionality lets us ignore the normalization constant:

$$p(\theta; a, b) \propto \theta^{a-1} (1-\theta)^{b-1}$$
.

CSC2515 Lec8 5 / 51

• Beta distribution for various values of a, b:

- Some observations:
  - The expectation  $\mathbb{E}[\theta] = a/(a+b)$ .
  - The distribution gets more peaked when a and b are large.
  - The uniform distribution is the special case where a = b = 1.
- The main thing the beta distribution is used for is as a prior for the Bernoulli distribution.

CSC2515 Lec8 6 / 51

• Computing the posterior distribution:

$$p(\theta \mid \mathcal{D}) \propto p(\theta)p(\mathcal{D} \mid \theta)$$

$$\propto \left[\theta^{a-1}(1-\theta)^{b-1}\right] \left[\theta^{N_H}(1-\theta)^{N_T}\right]$$

$$= \theta^{a-1+N_H}(1-\theta)^{b-1+N_T}.$$

- This is just a beta distribution with parameters  $N_H + a$  and  $N_T + b$ .
- The posterior expectation of  $\theta$  is:

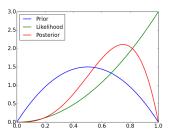

$$\mathbb{E}[\theta \mid \mathcal{D}] = \frac{N_H + a}{N_H + N_T + a + b}$$

- The parameters *a* and *b* of the prior can be thought of as pseudo-counts.
  - The reason this works is that the prior and likelihood have the same functional form. This phenomenon is known as conjugacy, and it's very useful.

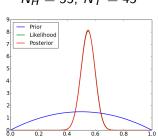

CSC2515 Lec8 7 / 5

Bayesian inference for the coin flip example:

Small data setting 
$$N_H = 2$$
.  $N_T = 0$ 

Large data setting  $N_H = 55$ .  $N_T = 45$ 

When you have enough observations, the data overwhelm the prior.

CSC2515 Lec8 8 / 51

- What do we actually do with the posterior?
- The posterior predictive distribution is the distribution over future observables given the past observations. We compute this by marginalizing out the parameter(s):

$$p(\mathcal{D}' | \mathcal{D}) = \int p(\boldsymbol{\theta} | \mathcal{D}) p(\mathcal{D}' | \boldsymbol{\theta}) d\boldsymbol{\theta}.$$
 (1)

• For the coin flip example:

$$\theta_{\text{pred}} = \Pr(x' = H \mid \mathcal{D})$$

$$= \int p(\theta \mid \mathcal{D}) \Pr(x' = H \mid \theta) d\theta$$

$$= \int \text{Beta}(\theta; N_H + a, N_T + b) \cdot \theta d\theta$$

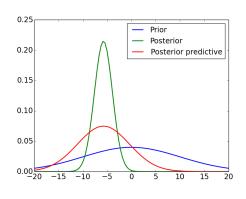

$$= \mathbb{E}_{\text{Beta}(\theta; N_H + a, N_T + b)}[\theta]$$

$$= \frac{N_H + a}{N_H + N_T + a + b},$$
(2)

CSC2515 Lec8 9 / 51

#### Bayesian estimation of the mean temperature in Toronto

- Assume observations are i.i.d. Gaussian with known standard deviation  $\sigma$  and unknown mean  $\mu$
- Broad Gaussian prior over  $\mu$ , centered at 0
- We can compute the posterior and posterior predictive distributions analytically (full derivation in notes)
- Why is the posterior predictive distribution more spread out than the posterior distribution?

CSC2515 Lec8 10 / 51

#### Comparison of maximum likelihood and Bayesian parameter estimation

- Some advantages of the Bayesian approach
  - More robust to data sparsity
  - Incorporate prior knowledge
  - Smooth the predictions by averaging over plausible explanations
- Problem: maximum likelihood is an optimization problem, while Bayesian parameter estimation is an integration problem
  - This means maximum likelihood is much easier in practice, since we can just do gradient descent
  - Automatic differentiation packages make it really easy to compute gradients
  - There aren't any comparable black-box tools for Bayesian parameter estimation (although Stan can do quite a lot)

CSC2515 Lec8 11 / 51

- Maximum a-posteriori (MAP) estimation: find the most likely parameter settings under the posterior
- This converts the Bayesian parameter estimation problem into a maximization problem

$$\begin{split} \hat{\boldsymbol{\theta}}_{\mathrm{MAP}} &= \arg\max_{\boldsymbol{\theta}} \; p(\boldsymbol{\theta} \,|\, \mathcal{D}) \\ &= \arg\max_{\boldsymbol{\theta}} \; p(\boldsymbol{\theta}) \, p(\mathcal{D} \,|\, \boldsymbol{\theta}) \\ &= \arg\max_{\boldsymbol{\theta}} \; \log p(\boldsymbol{\theta}) + \log p(\mathcal{D} \,|\, \boldsymbol{\theta}) \end{split}$$

CSC2515 Lec8 12 / 51

Joint probability in the coin flip example:

$$\begin{aligned} \log p(\theta, \mathcal{D}) &= \log p(\theta) + \log p(\mathcal{D} \mid \theta) \\ &= \text{const} + (a - 1) \log \theta + (b - 1) \log(1 - \theta) + N_H \log \theta + N_T \log(1 - \theta) \\ &= \text{const} + (N_H + a - 1) \log \theta + (N_T + b - 1) \log(1 - \theta) \end{aligned}$$

Maximize by finding a critical point

$$0 = \frac{\mathrm{d}}{\mathrm{d}\theta} \log p(\theta, \mathcal{D}) = \frac{N_H + a - 1}{\theta} - \frac{N_T + b - 1}{1 - \theta}$$

• Solving for  $\theta$ ,

$$\hat{\theta}_{\mathrm{MAP}} = \frac{N_H + a - 1}{N_H + N_T + a + b - 2}$$

13/51

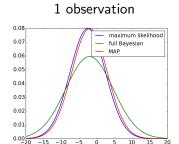

Comparison of estimates in the coin flip example:

	Formula	$N_H=2, N_T=0$	$N_H = 55, N_T = 45$
$\hat{ heta}_{ m ML}$	$rac{N_H}{N_H + N_T}$	1	$\frac{55}{100} = 0.55$
$\theta_{\mathrm{pred}}$	$\frac{N_H + a}{N_H + N_T + a + b}$	$\frac{4}{6} \approx 0.67$	$\tfrac{57}{104}\approx 0.548$
$\hat{ heta}_{ ext{MAP}}$	$\frac{N_{H} + a - 1}{N_{H} + N_{T} + a + b - 2}$	$\frac{3}{4} = 0.75$	$\frac{56}{102}\approx 0.549$

 $\hat{\theta}_{\mathrm{MAP}}$  assigns nonzero probabilities as long as a,b>1.

Generative Classifiers and Naïve Bayes

## Generative vs. Discriminative

#### Two approaches to classification:

Discriminative

Generative

CSC2515 Lec8 17 / 5

#### Generative vs. Discriminative

#### Two approaches to classification:

- Discriminative: directly learn to predict t as a function of x.
  - Sometimes this means modeling  $p(t | \mathbf{x})$  (e.g. logistic regression).
  - Sometimes this means learning a decision rule without a probabilistic interpretation (e.g. KNN, SVM).
- Generative: model the data distribution for each class separately, and make predictions using posterior inference.
  - Fit models of p(t) and  $p(\mathbf{x} \mid t)$ .
  - Infer the posterior  $p(t | \mathbf{x})$  using Bayes' Rule.

CSC2515 Lec8 18 / 51

## Bayes Classifier

 Bayes classifier: given features x, we compute the posterior class probabilities using Bayes' Rule:

$$\underbrace{p(t \mid \mathbf{x})}_{p(t \mid \mathbf{x})} = \underbrace{\frac{\underset{\text{likelihood}}{\text{class}}}{p(\mathbf{x} \mid t)}}_{\underset{\text{constant}}{p(\mathbf{x})}} \underbrace{\frac{\underset{\text{class}}{\text{class}}}{p(\mathbf{x})}}_{p(\mathbf{x})}$$

- Requires fitting  $p(\mathbf{x} \mid t)$  and p(t)
- How can we compute p(x) for binary classification?

$$p(\mathbf{x}) = p(\mathbf{x} \mid t = 0) \Pr(t = 0) + p(\mathbf{x} \mid t = 1) \Pr(t = 1)$$

 Note: sometimes it's more convenient to just compute the numerator and normalize.

CSC2515 Lec8 19 / 51

## Naïve Bayes

- **Example:** want to classify emails into spam (t = 1) or non-spam (t = 0) based on the words they contain.
  - Use bag-of-words features, i.e. a binary vector  $\mathbf{x}$  where entry  $x_j = 1$  if word j appeared in the email. (Assume a dictionary of D words.)
- Estimating the prior p(t) is easy (e.g. maximum likelihood).
- **Problem:**  $p(\mathbf{x} \mid t)$  is a joint distribution over D binary random variables, which requires  $2^D$  entries to specify directly!
- We'd like to impose structure on the distribution such that:
  - it can be compactly represented
  - learning and inference are both tractable
- Probabilistic graphical models are a powerful and wide-ranging class of techniques for doing this. We'll just scratch the surface here, but you'll learn about them in detail in CSC2506.

CSC2515 Lec8 20 / 51

## Naïve Bayes

- Naïve Bayes makes the assumption that the word features x<sub>j</sub> are conditionally independent given the class t.
  - This means  $x_i$  and  $x_j$  are independent under the conditional distribution  $p(\mathbf{x} \mid t)$ .
  - Note: this doesn't mean they're independent. (E.g., "Viagra" and "cheap" are correlated insofar as they both depend on t.)
  - Mathematically, this means the distribution factorizes:

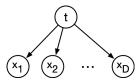

$$p(t,x_1,\ldots,x_D)=p(t)\,p(x_1\,|\,t)\cdots p(x_D\,|\,t).$$

- Compact representation of the joint distribution
  - Prior probability of class:  $Pr(t=1) = \phi$
  - ullet Conditional probability of word feature given class:  $\Pr(x_j=1\,|\,t)= heta_{jt}$
  - 2D + 1 parameters total

CSC2515 Lec8 21 / 51

# Bayes Nets (Optional)

 We can represent this model using an directed graphical model, or Bayesian network:

- This graph structure means the joint distribution factorizes as a product of conditional distributions for each variable given its parent(s).
- Intuitively, you can think of the edges as reflecting a causal structure.
   But mathematically, we can't infer causality without additional assumptions.
- You'll learn a lot about graphical models in CSC2506.

CSC2515 Lec8 22 / 51

## Naïve Bayes: Learning

 The parameters can be learned efficiently because the log-likelihood decomposes into independent terms for each feature.

$$\begin{split} \ell(\boldsymbol{\theta}) &= \sum_{i=1}^{N} \log p(t^{(i)}, \mathbf{x}^{(i)}) \\ &= \sum_{i=1}^{N} \log p(t^{(i)}) \prod_{j=1}^{D} p(x_{j}^{(i)} \mid t^{(i)}) \\ &= \sum_{i=1}^{N} \left[ \log p(t^{(i)}) + \sum_{j=1}^{D} \log p(x_{j}^{(i)} \mid t^{(i)}) \right] \\ &= \underbrace{\sum_{i=1}^{N} \log p(t^{(i)})}_{\text{Bernoulli log-likelihood}} + \sum_{j=1}^{D} \underbrace{\sum_{i=1}^{N} \log p(x_{j}^{(i)} \mid t^{(i)})}_{\text{Bernoulli log-likelihood}} \end{split}$$

 Each of these log-likelihood terms depends on different sets of parameters, so they can be optimized independently.

CSC2515 Lec8 23 / 51

# Naïve Bayes: Learning

- Want to maximize  $\sum_{i=1}^{N} \log p(x_j^{(i)} | t^{(i)})$
- This is a minor variant of our coin flip example. Let  $\theta_{ab} = \Pr(x_i = a \mid t = b)$ . Note  $\theta_{1b} = 1 \theta_{0b}$ .
- Log-likelihood:

$$\begin{split} \sum_{i=1}^N \log p(x_j^{(i)} \,|\: t^{(i)}) &= \sum_{i=1}^N t^{(i)} x_j^{(i)} \log \theta_{11} + \sum_{i=1}^N t^{(i)} (1 - x_j^{(i)}) \log (1 - \theta_{11}) \\ &+ \sum_{i=1}^N (1 - t^{(i)}) x_j^{(i)} \log \theta_{10} + \sum_{i=1}^N (1 - t^{(i)}) (1 - x_j^{(i)}) \log (1 - \theta_{10}) \end{split}$$

Obtain maximum likelihood estimates by setting derivatives to zero:

$$\theta_{11} = \frac{N_{11}}{N_{11} + N_{01}}$$
  $\theta_{10} = \frac{N_{10}}{N_{10} + N_{00}}$ 

where  $N_{ab}$  is the counts for  $x_i = a$  and t = b.

CSC2515 Lec8 24 / 51

## Naïve Bayes: Inference

- We predict the category by performing inference in the model.
- Apply Bayes' Rule:

$$p(t | \mathbf{x}) = \frac{p(t) p(\mathbf{x} | t)}{\sum_{t'} p(t') p(\mathbf{x} | t')}$$

$$= \frac{p(t) \prod_{j=1}^{D} p(x_j | t)}{\sum_{t'} p(t') \prod_{j=1}^{D} p(x_j | t')}$$

- We need not compute the denominator if we're simply trying to determine the mostly likely *t*.
- Shorthand notation:

$$p(t \mid \mathbf{x}) \propto p(t) \prod_{j=1}^{D} p(x_j \mid t)$$

CSC2515 Lec8 25 / 51

## Naïve Bayes: Decisions

- Once we compute  $p(t | \mathbf{x})$ , what do we do with it?
- Sometimes we want to make a single prediction or decision *y*. This is a decision theory problem, just like when we analyzed the bias/variance/Bayes-error decomposition.
  - Define a loss function  $\mathcal{L}(y, t)$  and choose  $y_* = \arg\min_y \mathbb{E}[\mathcal{L}(y, t) | \mathbf{x}]$ .
- Examples
  - Squared error loss: choose  $y_\star = \mathbb{E}[t \,|\, \mathbf{x}]$
  - 0-1 loss: choose the most likely category
  - Cross-entropy loss: return the probability  $y = \Pr(t = 1 \,|\, \mathbf{x})$
  - Asymmetric loss (e.g. false positives are much worse than false negatives for spam filtering): apply a threshold other than 0.5.
    - Warning: this is theoretically tidy, but doesn't really work unless you're careful to obtain calibrated posterior probabilities.
    - "Calibrated" means all the times you predict (say)  $\Pr(t = k \mid \mathbf{x}) = 0.9$  should be correct 90% on average.
    - Naïve Bayes is generally not calibrated due to the "naïve" conditional independence assumption.

CSC2515 Lec8 26 / 51

## Naïve Bayes

- Naïve Bayes is an amazingly cheap learning algorithm!
- Training time: estimate parameters using maximum likelihood
  - Compute co-occurrence counts of each feature with the labels.
  - Requires only one pass through the data!
- Test time: apply Bayes' Rule
  - Cheap because of the model structure. (For more general models, Bayesian inference can be very expensive and/or complicated.)
- We covered the Bernoulli case for simplicity. But our analysis easily extends to other probability distributions.
- Unfortunately, it's usually less accurate in practice compared to discriminative models.
  - The problem is the "naïve" independence assumption.
  - We're covering it primarily as a stepping stone towards latent variable models.

CSC2515 Lec8 27 / 51

Gaussian Discriminant Analysis

#### Motivation

- Generative models model p(t) and  $p(\mathbf{x} \mid t)$
- Recall that  $p(\mathbf{x} | t = k)$  may be very complex

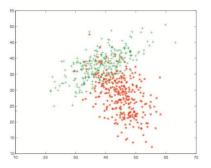

$$p(x_1, \dots, x_D \mid t) = p(x_1 \mid x_2, \dots, x_D, t) \dots p(x_{D-1} \mid x_D, t) p(x_D \mid t)$$

- Naïve Bayes used a conditional independence assumption to make everything tractable.
- For continuous inputs, we can instead make it tractable by using a simple distribution: multivariate Gaussians.

CSC2515 Lec8 29 / 51

# Classification: Diabetes Example

• Observation per patient: White blood cell count & glucose value.

• How can we model  $p(\mathbf{x} | t = k)$ ? Multivariate Gaussian

CSC2515 Lec8 30 / 51

## Multivariate Parameters

Mean

$$oldsymbol{\mu} = \mathbb{E}[\mathbf{x}] = egin{pmatrix} \mu_1 \ dots \ \mu_D \end{pmatrix}$$

Covariance

$$\mathbf{\Sigma} = \mathsf{Cov}(\mathbf{x}) = \mathbb{E}[(\mathbf{x} - \boldsymbol{\mu})^{\top}(\mathbf{x} - \boldsymbol{\mu})] = \begin{pmatrix} \sigma_1^2 & \sigma_{12} & \cdots & \sigma_{1D} \\ \sigma_{12} & \sigma_2^2 & \cdots & \sigma_{2D} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{D1} & \sigma_{D2} & \cdots & \sigma_D^2 \end{pmatrix}$$

 These statistics uniquely define a multivariate Gaussian distribution. (This is not true for distributions in general!)

CSC2515 Lec8 31 / 51

#### Multivariate Gaussian Distribution

•  $\mathbf{x} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , a multivariate Gaussian (or multivariate normal) distribution is defined as

$$p(\mathbf{x}) = \frac{1}{(2\pi)^{D/2} |\mathbf{\Sigma}|^{1/2}} \exp\left[-\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})^{\top} \mathbf{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu})\right]$$

• Mahalanobis distance  $(\mathbf{x} - \boldsymbol{\mu})^{\top} \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu})$  measures the distance from  $\mathbf{x}$  to  $\boldsymbol{\mu}$  in a space stretched according to  $\boldsymbol{\Sigma}$ .

CSC2515 Lec8 32 / 51

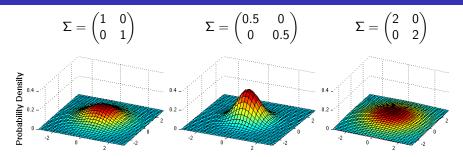

Figure: Probability density function

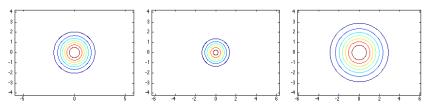

Figure: Contour plot of the pdf

CSC2515 Lec8 33 / 51

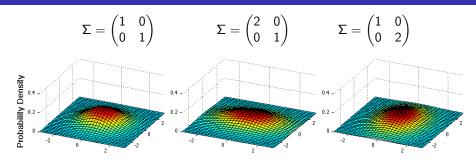

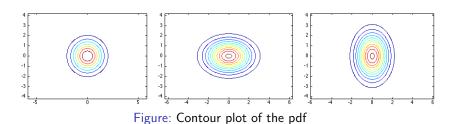

Figure: Probability density function

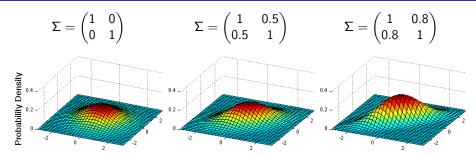

Figure: Probability density function

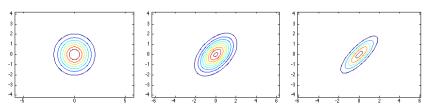

Figure: Contour plot of the pdf

CSC2515 Lec8 35 / 51

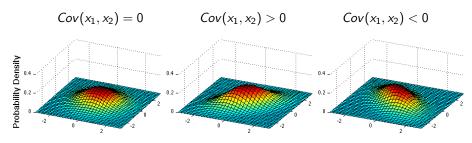

Figure: Probability density function

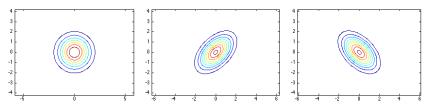

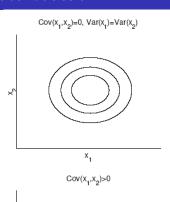

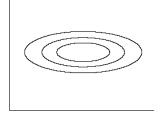

Figure: Contour plot of the pdf

CSC2515 Lec8 36 / 51

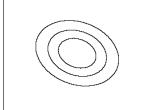

#### Bivariate Gaussian

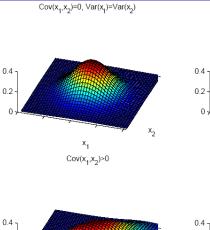

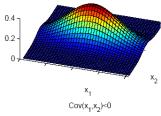

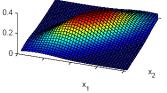

CSC2515 Lec8 37 / 5

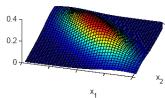

#### Bivariate Gaussian

#### Gaussian Discriminant Analysis

- Gaussian Discriminant Analysis in its general form assumes that  $p(\mathbf{x}|t)$  is distributed according to a multivariate Gaussian distribution
- Multivariate Gaussian distribution:

$$p(\mathbf{x} \mid t = k) = \frac{1}{(2\pi)^{D/2} |\mathbf{\Sigma}_k|^{1/2}} \exp\left[-\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu}_k)^T \mathbf{\Sigma}_k^{-1} (\mathbf{x} - \boldsymbol{\mu}_k)\right]$$

where  $|\Sigma_k|$  denotes the determinant of the matrix.

- Each class k has associated mean vector  $\mu_k$  and covariance matrix  $\Sigma_k$
- How many parameters?
  - Each  $\mu_{\nu}$  has D parameters, for DK total.
  - Each  $\Sigma_k$  has  $\mathcal{O}(D^2)$  parameters, for  $\mathcal{O}(D^2K)$  could be hard to estimate (more on that later).

39 / 51

## GDA: Learning

- Learn the parameters for each class using maximum likelihood
- For simplicity, assume binary classification

$$p(t \mid \phi) = \phi^t (1 - \phi)^{1-t}$$

• You can compute the ML estimates in closed form ( $\phi$  and  $\mu_k$  are easy,  $\Sigma_k$  is tricky)

$$\phi = \frac{1}{N} \sum_{i=1}^{N} r_1^{(i)}$$

$$\mu_k = \frac{\sum_{i=1}^{N} r_k^{(i)} \cdot \mathbf{x}^{(i)}}{\sum_{i=1}^{N} r_k^{(i)}}$$

$$\Sigma_k = \frac{1}{\sum_{i=1}^{N} r_k^{(i)}} \sum_{i=1}^{N} r_k^{(i)} (\mathbf{x}^{(i)} - \mu_k) (\mathbf{x}^{(i)} - \mu_k)^{\top}$$

$$r_k^{(i)} = \mathbb{1}[t^{(i)} = k]$$

CSC2515 Lec8 40 / 51

## **GDA** Decision Boundary

 Recall: for Bayes classifiers, we compute the decision boundary with Bayes' Rule:

$$p(t \mid \mathbf{x}) = \frac{p(t) p(\mathbf{x} \mid t)}{\sum_{t'} p(t') p(\mathbf{x} \mid t')}$$

• Plug in the Gaussian  $p(\mathbf{x} \mid t)$ :

$$\log p(t_k|\mathbf{x}) = \log p(\mathbf{x}|t_k) + \log p(t_k) - \log p(\mathbf{x})$$

$$= -\frac{D}{2}\log(2\pi) - \frac{1}{2}\log|\mathbf{\Sigma}_k| - \frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_k)^{\top}\mathbf{\Sigma}_k^{-1}(\mathbf{x} - \boldsymbol{\mu}_k) + \log p(t_k) - \log p(\mathbf{x})$$

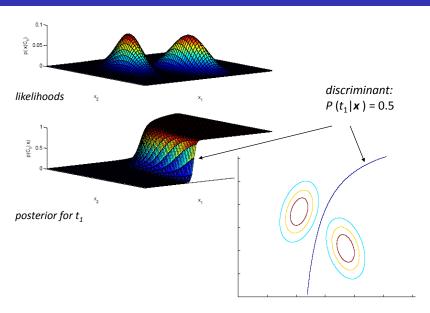

Decision boundary:

$$(\mathbf{x} - \boldsymbol{\mu}_k)^{\top} \boldsymbol{\Sigma}_k^{-1} (\mathbf{x} - \boldsymbol{\mu}_k) = (\mathbf{x} - \boldsymbol{\mu}_\ell)^{\top} \boldsymbol{\Sigma}_\ell^{-1} (\mathbf{x} - \boldsymbol{\mu}_\ell) + \mathrm{Const}$$

- What's the shape of the boundary?
  - We have a quadratic function in x, so the decision boundary is a conic section!

CSC2515 Lec8 41 / 51

# **GDA** Decision Boundary

CSC2515 Lec8 42 / 53

## **GDA** Decision Boundary

Our equation for the decision boundary:

$$(\mathbf{x} - \boldsymbol{\mu}_k)^{\top} \boldsymbol{\Sigma}_k^{-1} (\mathbf{x} - \boldsymbol{\mu}_k) = (\mathbf{x} - \boldsymbol{\mu}_\ell)^{\top} \boldsymbol{\Sigma}_\ell^{-1} (\mathbf{x} - \boldsymbol{\mu}_\ell) + \mathrm{Const}$$

• Expand the product and factor out constants (w.r.t. x):

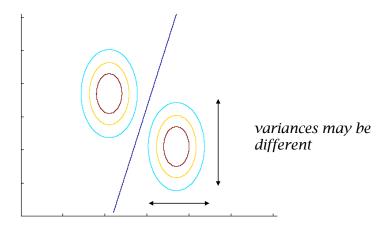

$$\mathbf{x}^{\top} \mathbf{\Sigma}_k^{-1} \mathbf{x} - 2 \boldsymbol{\mu}_k^{\top} \mathbf{\Sigma}_k^{-1} \mathbf{x} = \mathbf{x}^{\top} \mathbf{\Sigma}_{\ell}^{-1} \mathbf{x} - 2 \boldsymbol{\mu}_{\ell}^{\top} \mathbf{\Sigma}_{\ell}^{-1} \mathbf{x} + \mathrm{Const}$$

- What if all classes share the same covariance Σ?
  - We get a linear decision boundary!

$$-2\boldsymbol{\mu}_k^{\top} \boldsymbol{\Sigma}^{-1} \mathbf{x} = -2\boldsymbol{\mu}_{\ell}^{\top} \boldsymbol{\Sigma}^{-1} \mathbf{x} + \text{Const}$$
$$(\boldsymbol{\mu}_k - \boldsymbol{\mu}_{\ell})^{\top} \boldsymbol{\Sigma}^{-1} \mathbf{x} = \text{Const}$$

CSC2515 Lec8 43 / 51

# GDA Decision Boundary: Shared Covariances

CSC2515 Lec8 44 / 51

## GDA vs Logistic Regression

• Binary classification: If you examine  $p(t = 1 | \mathbf{x})$  under GDA and assume  $\Sigma_0 = \Sigma_1 = \Sigma$ , you will find that it looks like this:

$$p(t \mid \mathbf{x}, \phi, \boldsymbol{\mu}_0, \boldsymbol{\mu}_1, \boldsymbol{\Sigma}) = \frac{1}{1 + \exp(-\mathbf{w}^T \mathbf{x} - b)}$$

where  $(\mathbf{w}, b)$  are chosen based on  $(\phi, \boldsymbol{\mu}_0, \boldsymbol{\mu}_1, \boldsymbol{\Sigma})$ .

Same model as logistic regression!

#### GDA vs Logistic Regression

When should we prefer GDA to LR, and vice versa?

- GDA makes a stronger modeling assumption: assumes class-conditional data is multivariate Gaussian
  - If this is true, GDA is asymptotically efficient (best model in limit of large N)
  - If it's not true, the quality of the predictions might suffer.
- Many class-conditional distributions lead to logistic classifier.
  - When these distributions are non-Gaussian (i.e., almost always), LR usually beats GDA
- GDA can handle easily missing features (how do you do that with LR?)

CSC2515 Lec8 46 / 51

## Gaussian Naive Bayes

- What if x is high-dimensional?
  - The  $\Sigma_k$  have  $\mathcal{O}(D^2K)$  parameters, which can be a problem if D is large.
  - We already saw we can save some a factor of K by using a shared covariance for the classes.
  - Any other idea you can think of?
- Naive Bayes: Assumes features independent given the class

$$p(\mathbf{x} | t = k) = \prod_{j=1}^{D} p(x_j | t = k)$$

- Assuming likelihoods are Gaussian, how many parameters required for Naive Bayes classifier?
  - This is equivalent to assuming the  $x_j$  are uncorrelated, i.e.  $\Sigma$  is diagonal.
  - Hence, only D parameters for  $\Sigma$ !

CSC2515 Lec8 47 / 51

#### Gaussian Naïve Bayes

Gaussian Naïve Bayes classifier assumes that the likelihoods are Gaussian:

$$p(x_j \mid t = k) = \frac{1}{\sqrt{2\pi}\sigma_{jk}} \exp\left[\frac{-(x_j - \mu_{jk})^2}{2\sigma_{jk}^2}\right]$$

(this is just a 1-dim Gaussian, one for each input dimension)

- Model the same as GDA with diagonal covariance matrix
- Maximum likelihood estimate of parameters

$$\mu_{jk} = \frac{\sum_{i=1}^{N} r_k^{(i)} x_j^{(i)}}{\sum_{i=1}^{N} r_k^{(i)}}$$

$$\sigma_{jk}^2 = \frac{\sum_{i=1}^{N} r_k^{(i)} (x_j^{(i)} - \mu_{jk})^2}{\sum_{i=1}^{N} r_k^{(i)}}$$

$$r_k^{(i)} = \mathbb{1}[t^{(i)} = k]$$

48 / 51

#### Decision Boundary: Isotropic

- We can go even further and assume the covariances are spherical, or isotropic.
- In this case:  $\Sigma = \sigma^2 I$  (just need one parameter!)
- Going back to the class posterior for GDA:

$$\log p(t_k|\mathbf{x}) = \log p(\mathbf{x}|t_k) + \log p(t_k) - \log p(\mathbf{x})$$

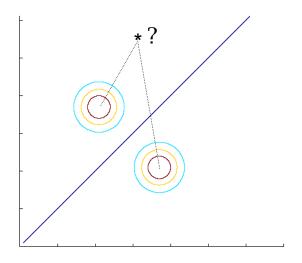

$$= -\frac{D}{2}\log(2\pi) - \frac{1}{2}\log|\mathbf{\Sigma}_k^{-1}| - \frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_k)^{\top}\mathbf{\Sigma}_k^{-1}(\mathbf{x} - \boldsymbol{\mu}_k) + \log p(t_k) - \log p(\mathbf{x})$$

• Suppose for simplicity that p(t) is uniform. Plugging in  $\Sigma = \sigma^2 \mathbf{I}$  and simplifying a bit,

$$egin{aligned} \log p(t_k \,|\, \mathbf{x}) - \log p(t_\ell \,|\, \mathbf{x}) &= -rac{1}{2\sigma^2} \left[ (\mathbf{x} - oldsymbol{\mu}_k)^ op (\mathbf{x} - oldsymbol{\mu}_k) - (\mathbf{x} - oldsymbol{\mu}_\ell)^ op (\mathbf{x} - oldsymbol{\mu}_\ell) 
ight] \ &= -rac{1}{2\sigma^2} \left[ \|\mathbf{x} - oldsymbol{\mu}_k\|^2 - \|\mathbf{x} - oldsymbol{\mu}_\ell\|^2 
ight] \end{aligned}$$

## Decision Boundary: Isotropic

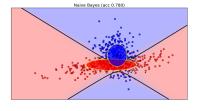

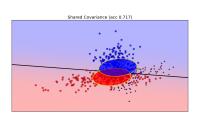

• The decision boundary bisects the class means!
